## April 10, 2017 — 24. Constraint Satisfaction Problems: Backtracking

24.1 CSP Algorithms

24.2 Naive Backtracking

24.3 Variable and Value Orders

24.4 Summary

## Constraint Satisfaction Problems: Overview

Chapter overview: constraint satisfaction problems:

- ▶ 22.–23. Introduction
- ▶ 24.–26. Basic Algorithms
  - ▶ 24. Backtracking
  - ▶ 25. Arc Consistency
  - ▶ 26. Path Consistency
- ▶ 27.–28. Problem Structure

## 24.1 CSP Algorithms

## CSP Algorithms

In the following chapters, we consider **algorithms for solving** constraint networks.

basic concepts:

- ▶ **search**: check partial assignments systematically
- ▶ **backtracking**: discard inconsistent partial assignments
- ▶ **inference**: derive equivalent, but tighter constraints to reduce the size of the search space

## 24.2 Naive Backtracking

### Naive Backtracking (= Without Inference)

**function** NaiveBacktracking( $\mathcal{C}, \alpha$ ):

$\langle V, \text{dom}, (R_{uv}) \rangle := \mathcal{C}$

**if**  $\alpha$  is inconsistent with  $\mathcal{C}$ :

**return inconsistent**

**if**  $\alpha$  is a total assignment:

**return**  $\alpha$

select **some variable**  $v$  for which  $\alpha$  is not defined

**for each**  $d \in \text{dom}(v)$  **in some order**:

$\alpha' := \alpha \cup \{v \mapsto d\}$

$\alpha'' := \text{NaiveBacktracking}(\mathcal{C}, \alpha')$

**if**  $\alpha'' \neq \text{inconsistent}$ :

**return**  $\alpha''$

**return inconsistent**

**input**: constraint network  $\mathcal{C}$  and partial assignment  $\alpha$  for  $\mathcal{C}$

(first invocation: empty assignment  $\alpha = \emptyset$ )

**result**: solution of  $\mathcal{C}$  or **inconsistent**

### Is This a New Algorithm?

We have already seen this algorithm:

**Backtracking corresponds to depth-first search** (Chapter 12) with the following state space:

- ▶ **states**: consistent partial assignments
- ▶ **initial state**: empty assignment  $\emptyset$
- ▶ **goal states**: consistent total assignments
- ▶ **actions**:  $\text{assign}_{v,d}$  assigns value  $d \in \text{dom}(v)$  to variable  $v$
- ▶ **action costs**: all 0 (all solutions are of equal quality)
- ▶ **transitions**:
  - ▶ for each non-total assignment  $\alpha$ , choose variable  $v = \text{select}(\alpha)$  that is unassigned in  $\alpha$
  - ▶ **transition**  $\alpha \xrightarrow{\text{assign}_{v,d}} \alpha \cup \{v \mapsto d\}$  for each  $d \in \text{dom}(v)$

## Why Depth-First Search?

Depth-first search is particularly well-suited for CSPs:

- ▶ path length **bounded** (by the number of variables)
- ▶ solutions located at **the same depth** (lowest search layer)
- ▶ state space is directed **tree**, initial state is the root
  - ↪ **no duplicates** (Why?)

Hence none of the problematic cases for depth-first search occurs.

## Naive Backtracking: Example

Consider the constraint network for the following graph coloring problem:

## Naive Backtracking: Example

search tree for naive backtracking with

- ▶ **fixed variable order**  $v_1, v_7, v_4, v_5, v_6, v_3, v_2$
- ▶ **alphabetical** order of the values

(without inconsistent nodes; continued at goal nodes)

## Naive Backtracking: Discussion

- ▶ Naive backtracking often has to exhaustively explore **similar** search paths (i.e., partial assignments that are identical except for a few variables).
- ▶ “Critical” variables are not recognized and hence considered for assignment (too) late.
- ▶ Decisions that necessarily lead to constraint violations are only recognized when all variables involved in the constraint have been assigned.

↪ more intelligence by **focusing on critical decisions** and by **inference** of consequences of previous decisions

## 24.3 Variable and Value Orders

## Naive Backtracking

```

function NaiveBacktracking( $\mathcal{C}, \alpha$ ):
   $\langle V, \text{dom}, (R_{uv}) \rangle := \mathcal{C}$ 
  if  $\alpha$  is inconsistent with  $\mathcal{C}$ :
    return inconsistent
  if  $\alpha$  is a total assignment:
    return  $\alpha$ 
  select some variable  $v$  for which  $\alpha$  is not defined
  for each  $d \in \text{dom}(v)$  in some order:
     $\alpha' := \alpha \cup \{v \mapsto d\}$ 
     $\alpha'' := \text{NaiveBacktracking}(\mathcal{C}, \alpha')$ 
    if  $\alpha'' \neq \text{inconsistent}$ :
      return  $\alpha''$ 
  return inconsistent

```

## Variable and Value Orders

### variable orders:

- ▶ Backtracking does not specify in which order **variables** are considered for assignment.
- ▶ Such orders can strongly influence the search space size and hence the search performance.  
 $\rightsquigarrow$  **example**: exercises

German: Variablenordnung

### value orders:

- ▶ Backtracking does not specify in which order the **values** of the selected variable  $v$  are considered.
- ▶ This is not as important because it **does not matter** in subtrees without a solution. (*Why not?*)
- ▶ **If** there is a solution in the subtree, then ideally a value that leads to a solution should be chosen. (*Why?*)

German: Werteordnung

## Static vs. Dynamic Orders

we distinguish:

- ▶ **static** orders (fixed prior to search)
- ▶ **dynamic** orders (selected variable or value order depends on the search state)

comparison:

- ▶ dynamic orders obviously more powerful
- ▶ static orders  $\rightsquigarrow$  no computational overhead during search

The following ordering criteria can be used statically, but are more effective combined with inference ( $\rightsquigarrow$  later) and used dynamically.

## Variable Orders

two common variable ordering criteria:

- ▶ **minimum remaining values:**  
prefer variables that have small **domains**
  - ▶ **intuition:** few subtrees  $\rightsquigarrow$  smaller tree
  - ▶ **extreme case:** only **one** value  $\rightsquigarrow$  forced assignment
- ▶ **most constraining variable:**  
prefer variables contained in **many** nontrivial constraints
  - ▶ **intuition:** constraints tested early  
 $\rightsquigarrow$  inconsistencies recognized early  $\rightsquigarrow$  smaller tree

**combination:** use minimum remaining values criterion, then most constraining variable criterion to break ties

## Value Orders

### Definition (conflict)

Let  $\mathcal{C} = \langle V, \text{dom}, (R_{uv}) \rangle$  be a constraint network.

For variables  $v \neq v'$  and values  $d \in \text{dom}(v)$ ,  $d' \in \text{dom}(v')$ , the assignment  $v \mapsto d$  is **in conflict** with  $v' \mapsto d'$  if  $\langle d, d' \rangle \notin R_{vv'}$ .

value ordering criterion for partial assignment  $\alpha$  and selected variable  $v$ :

- ▶ **minimum conflicts:** prefer values  $d \in \text{dom}(v)$  such that  $v \mapsto d$  causes as few conflicts as possible with variables that are unassigned in  $\alpha$

## 24.4 Summary

## Summary: Backtracking

basic search algorithm for constraint networks: **backtracking**

- ▶ extends the (initially empty) partial assignment step by step until an **inconsistency** or a **solution** is found
- ▶ is a form of **depth-first search**
- ▶ depth-first search particularly well-suited because state space is directed tree and all solutions at same (known) depth

## Summary: Variable and Value Orders

- ▶ **Variable orders** influence the performance of backtracking significantly.
  - ▶ goal: **critical** decisions as early as possible
- ▶ **Value orders** influence the performance of backtracking on **solvable** constraint networks significantly.
  - ▶ goal: **most promising** assignments first
